Homework 2

Section 10.9

#10 Let S_+ and S_- be the left and right shift operators on ℓ^2 . Show that $S_- = S_+^*$ and $S_+ = S_-^*$.

Proof. Both S_+ and S_- are in $\mathcal{B}(\ell^2)$ therefore they both have unique adjoints. Consider $x, y \in \ell^2$, then

$$\begin{aligned}\langle S_+x, y \rangle &= \sum_{n=1}^{\infty} ((S_+x)_n \cdot \overline{y_n}) \\ &= \sum_{n=2}^{\infty} (x_{n-1} \cdot \overline{y_n}) \\ &= \sum_{n=1}^{\infty} (x_n \cdot \overline{y_{n+1}}) \\ &= \sum_{n=1}^{\infty} (x_n \cdot \overline{(S_-y)_n}) \\ &= \langle x, S_-y \rangle\end{aligned}$$

This shows that $S_+^* = S_-$. Now since $S_+, S_- \in \mathcal{B}(\ell^2)$ it is true that $(S_+^*)^* = S_+$ or $S_-^* = S_+$. \square

#11 Let T be the Volterra integral operator $Tu = \int_0^x u(y) dy$ considered as an operator on $L^2(0, 1)$. Find T^* and $N(T^*)$.

Consider $u, v \in L^2(0, 1)$.

$$\begin{aligned}\langle Tu, v \rangle &= \int_0^1 Tu(x) \overline{v(x)} dx \\ &= \int_0^1 \int_0^x u(y) dy \overline{v(x)} dx \\ &= \int_0^1 \int_y^1 \overline{v(x)} dx u(y) dy \\ &= \int_0^1 \int_y^1 v(x) dx u(y) dy \\ &= \langle u, T^*v \rangle\end{aligned}$$

where

$$T^*v(y) = \int_y^1 v(x) dx$$

Since $T \in \mathcal{B}(L^2(0, 1))$ this is the unique adjoint of T .

In order to find $N(T^*)$ consider $u \in L^2(0, 1)$ such that

$$T^*u = 0$$

This implies that

$$T^*v(y) = \int_y^1 v(x) dx = 0$$

for every $y \in (0, 1)$. Using the Fundamental Theorem of Calculus for L^2 functions it can be seen that

$$0 = -v(y) + v(1)$$

This implies that $v(y) = v(1)$ for every $y \in (0, 1)$ or equivalently that v is a constant function. Therefore the $N(T^*) = \{v \in L^2(0, 1) : v = c \text{ for some } c \in \mathbb{R}\}$.

#12 Suppose $T \in \mathcal{B}(\mathbf{H})$ is self-adjoint and there exists a constant $c > 0$ such that $\|Tu\| \geq c\|u\|$ for all $u \in \mathbf{H}$. Show that there exists a solution of $Tu = f$ for all $f \in \mathbf{H}$. Show by example that the conclusion may be false if the assumption of self-adjointness is removed.

Proof. This conclusion may be false if that operator is not self-adjoint. Consider the operator S_+ on ℓ^2 . We have already shown that $S_+^* = S_-$ so S_+ is not self-adjoint. However $\|S_+x\| = \|x\|$ for all $x \in \ell^2$, so with $c = 1$ S_+ satisfies $\|S_+x\| \geq c\|x\|$ for all $x \in \ell^2$. However $R(S_+) = \{x \in \ell^2 : x_1 = 0\}$, so $S_+u = x$ will not have a solution if $x_1 \neq 0$. \square

#13 Let M be the multiplication operator $Mu(x) = xu(x)$ in $L^2(0,1)$. Show that $R(M)$ is dense but not closed.

Proof. First of all note that M is self adjoint, this is because $M^*u(x) = \bar{x}u(x) = xu(x) = Mu(x)$ on $x \in (0,1)$. Therefore $N(M^*) = N(M)$. By definition

$$N(M) = \left\{ x \in L^2(0,1) : \|xu(x)\|_{L^2} = 0 \forall x \in (0,1) \right\}$$

Equivalently this implies that

$$\int_0^1 |xu(x)|^2 dx = 0$$

which is the same as saying that $u(x) = 0$ almost everywhere. This shows that $N(M) = \{0\} = N(M^*)$. Now by proposition 10.3, we know that $\overline{R(M)} = N(M^*)^\perp = L^2(0,1)$. Thus the range of M is dense in $L^2(0,1)$.

Next I will construct a sequence in $R(M)$ that does not converge to a point in $R(M)$. That is I will find $u_n \in L^2(0,1)$ such that $Mu_n \rightarrow v \notin R(M)$. This will show that $R(M)$ is not closed. Let

$$u_n(x) = \begin{cases} 0 & x < \frac{1}{n} \\ x^{\frac{1}{n}-1} & x \geq \frac{1}{n} \end{cases}$$

First I will show that $u_n(x) \in L^2(0,1)$ for every $n \in \mathbb{N}$, $n \geq 3$. The fact that $n \geq 3$ is used when taking the antiderivative.

$$\begin{aligned} \int_0^1 |u_n(x)|^2 dx &= \int_{\frac{1}{n}}^1 \left| x^{\frac{1}{n}-1} \right|^2 dx \\ &= \int_{\frac{1}{n}}^1 x^{\frac{2}{n}-2} dx \\ &= \left(\frac{1}{\frac{2}{n}-1} x^{\frac{2}{n}-1} \right) \Big|_{x=\frac{1}{n}}^1 \\ &= \frac{1}{\frac{2}{n}-1} \left(1 - \left(\frac{1}{n} \right)^{\frac{2}{n}-1} \right) \\ &= \frac{n}{2-n} \left(1 - \left(\frac{1}{n} \right)^{\frac{2-n}{n}} \right) < \infty \end{aligned}$$

Second I will show that $Mu_n(x) \rightarrow 1$ in $L^2(0,1)$. Consider

$$\begin{aligned} \|Mu_n - 1\|_{L^2(0,1)}^2 &= \int_0^1 (Mu_n(x) - 1)^2 dx \\ &= \int_0^1 1 - 2Mu_n(x) + Mu_n(x)^2 dx \\ &= \int_0^1 1 dx - 2 \int_0^1 Mu_n(x) dx + \int_0^1 Mu_n(x)^2 dx \\ &= 1 - 2 \int_{\frac{1}{n}}^1 x^{\frac{1}{n}} dx + \int_{\frac{1}{n}}^1 x^{\frac{2}{n}} dx \\ &= 1 - 2 \left(\frac{1}{\frac{1}{n}+1} x^{\frac{1}{n}+1} \right) \Big|_{x=\frac{1}{n}}^1 + \left(\frac{1}{\frac{2}{n}+1} x^{\frac{2}{n}+1} \right) \Big|_{x=\frac{1}{n}}^1 \\ &= 1 - \frac{2}{\frac{1}{n}+1} \left(1 - \left(\frac{1}{n} \right)^{\frac{1}{n}+1} \right) + \frac{1}{\frac{2}{n}+1} \left(1 - \left(\frac{1}{n} \right)^{\frac{2}{n}+1} \right) \end{aligned}$$

Now consider the limit as $n \rightarrow \infty$.

$$\begin{aligned}
 \lim_{n \rightarrow \infty} \left(\|Mu_n - 1\|_{L^2(0,1)}^2 \right) &= \lim_{n \rightarrow \infty} \left(1 - \frac{2}{\frac{1}{n} + 1} \left(1 - \left(\frac{1}{n} \right)^{\frac{1}{n}+1} \right) + \frac{1}{\frac{2}{n} + 1} \left(1 - \left(\frac{1}{n} \right)^{\frac{2}{n}+1} \right) \right) \\
 &= 1 - \lim_{n \rightarrow \infty} \left(\frac{2}{\frac{1}{n} + 1} \left(1 - \left(\frac{1}{n} \right)^{\frac{1}{n}+1} \right) \right) + \lim_{n \rightarrow \infty} \left(\frac{1}{\frac{2}{n} + 1} \left(1 - \left(\frac{1}{n} \right)^{\frac{2}{n}+1} \right) \right) \\
 &= 1 - 2 + 1 = 0
 \end{aligned}$$

Therefore $Mu_n \rightarrow 1$ in $L^2(0,1)$. Lastly I will show that $1 \notin R(M)$ in order to show that $R(M)$ is not closed. \square

#15 An operator $T \in \mathcal{B}(\mathbf{H})$ is said to be normal if it commutes with its adjoint, i.e. $TT^* = T^*T$. Thus, for example, any self-adjoint, skew-adjoint, or unitary operator is normal. For a normal operator T show that

(a) $\|Tu\| = \|T^*u\|$ for every $u \in \mathbf{H}$.

Proof. Let $u \in \mathbf{H}$ and consider the following.

$$\begin{aligned}\|Tu\|^2 &= \langle Tu, Tu \rangle \\ &= \langle u, T^*Tu \rangle \\ &= \langle u, TT^*u \rangle \\ &= \langle u, (T^*)^*T^*u \rangle \\ &= \langle T^*u, T^*u \rangle \\ &= \|T^*u\|^2\end{aligned}$$

Therefore $\|Tu\| = \|T^*u\|$ for every $u \in \mathbf{H}$. □

(b) T is one to one if and only if it has dense range.

Proof. First note that when T is normal $N(T) = N(T^*)$. This can be seen by using part (a) and by letting $Tu = 0$, then $0 = \|Tu\| = \|T^*u\|$. This implies that $T^*u = 0$. Thus if $u \in N(T)$ then $u \in N(T^*)$. The opposite direction is equivalent, that is when $u \in N(T^*)$, then $u \in N(T)$. Now assume that T is one to one or equivalently $N(T) = \{0\}$. As was shown earlier this implies that $N(T^*) = \{0\}$ and by proposition 10.3 it is clear that

$$\overline{R(T)} = N(T^*)^\perp = \{0\}^\perp = \mathbf{H}$$

Therefore the range of T is dense in \mathbf{H} .

Finally let T have dense range, that is $\overline{R(T)} = \mathbf{H}$. This implies that $N(T^*)^\perp = \mathbf{H}$. Therefore for all $u \in \mathbf{H}$, $u \perp v$ for all $v \in N(T^*)$. The only element of \mathbf{H} that is orthogonal to all of \mathbf{H} is the zero element. Therefore $N(T^*) = \{0\}$ and it follows that $N(T) = \{0\}$, which shows that T is one to one. □

(c) Show that any multiplication operator or Fourier multiplication operator is normal in L^2 .

Let S be a multiplication operator on L^2 , then $Su(x) = w(x)u(x)$ for some $w \in L^\infty$. We have also shown that $S^*u(x) = \overline{w(x)}u(x)$. Now consider any $u \in L^2$.

$$\begin{aligned}S^*Su(x) &= S^*w(x)u(x) \\ &= \overline{w(x)}w(x)u(x) \\ &= w(x)\overline{w(x)}u(x) \\ &= S\overline{w(x)}u(x) \\ &= SS^*u(x)\end{aligned}$$

Therefore $S^*S = SS^*$ and S is normal.

Now let T be a Fourier multiplication operator. Then $T = F^{-1}SF$ where F is the Fourier Transform and S is some multiplication operator. Now all of these operators are in $\mathcal{B}(L^2)$ so $T^* = (F^{-1}SF)^* = F^*S^*(F^{-1})^*$. Also note that F is unitary so $F^* = F^{-1}$ and $(F^{-1})^* = F$. Thus $T^* = F^{-1}S^*F$. Now consider

$$\begin{aligned}TT^* &= F^{-1}SFF^{-1}S^*F \\ &= F^{-1}SS^*F\end{aligned}$$

Since S as a multiplication operator is normal

$$\begin{aligned} &= F^{-1}S^*SF \\ &= F^{-1}S^*FF^{-1}SF \\ &= T^*T \end{aligned}$$

Thus T is a normal operator.

- (b) Show that the shift operators S_+ and S_- are not normal in ℓ^2 .

Consider $x \in \ell^2$ such that $x_1 \neq 0$, then $S_-S_+x = x$ however $S_+S_-x = (0, x_2, x_3, \dots)$. Thus $S_+S_+^*x = S_+S_-x \neq S_-S_+x = S_+^*S_+x$. Therefore S_+ is not normal. Also $S_-S_-^*x = S_-S_+x \neq S_+S_-x = S_-^*S_-x$, so S_- is not normal either.

#19 If $T_n \in \mathcal{B}(X)$ and $\sum_{n=1}^{\infty} (\|T_n\|) < \infty$, show that the series $\sum_{n=1}^{\infty} (T_n)$ is uniformly convergent.
